

Main Project

Hyper-Local Data Disruption

Overview

Working in groups of two (or three) design and implement an interactive data visualization using body tracking information.

Overview

- Identify a unique dataset specific to a particular location, time, or context that is unlikely to be represented in broader datasets.
- Collect this data using any media, such as images, videos, sound recordings, or texts, to capture its unique characteristics.
- Create an interactive visualization that brings the collected data to life using body tracking information with either ml5.js, or TouchDesigner.

Datasets

- Sound recordings from a specific space
- Visual documentation of an area at different times of the day
- Image generated based on custom LoRA
- Personal or community narratives tied to a specific place
- Environmental data (e.g., microclimate data, unique flora)
- Speculation about data from the past that is underrepresented

Important dates

02.12.25	Concept Presentations
16.12.25	Mid-Point Check-in
06.01.26	Final Presentations
13.01.26	Documentation Deadline
16.01.26	Open House

christinegertsch How can data be made physically tangible? With the help of a single-player game, I have visualised the exponentially growing amounts of plastic waste in the sea.

The goal of the game is to resist the flow of plastic for as long as possible. If a piece falls to the ground, you lose a life. If possible, you catch the joker: a fishing line that would take centuries to degrade.

In the game, plastic pieces can also simply be removed from your field of vision – a solution that many countries have long considered valid (by exporting waste to poorer countries).

The game becomes physically more and more demanding over time until all game lives are used up – I realised while testing that it became almost an exergame ... 😊

The overwhelming nature of the game illustrates humanity's inability to cope with the problem of marine plastic pollution. The successive game levels are based on the calculated amounts of macroplastics that will enter the sea worldwide each year from 1950 to 2050.

After the game is over, the avatar stays in freeze and can only watch as the forecast continues until 2050.

Data source: International Energy Agency, World Energy Outlook 2015

The game has been designed as a landscape-format projection installation.

Technology:
– p5.js, d3.js
– Motion Tracking (ml5)
– Physics Engine (matter.js)
